Some VHF Bridge Applications

NORMAN L. RIEMENSCHNEIDER, Sales Engineer

Recognizing the gap that inevitably exists between the basic information offered in the instruction manual and the inherent potentialities of the instrument involved, this article is written with the intent of sharing our knowledge of the RX Meter Type 250-A and offering the benefit of our field experience.

For those not having a speaking acquaintance with the RX meter, we might briefly mention that it consists of a V.H.F. Schering bridge, signal generator, and a detector-indicator completely self-contained in one unit which measures impedances from 500 KC to 250 MC in terms of equivalent parallel resistance and parallel capacitance (or inductance). It will be shown that with these basic elements and some understanding of the principles involved, the bridge lends itself to many applications not immediately obvious.

Measurement of Transistors, Vacuum Tubes, Diodes and Biased Circuits

The RX Type 250-A Meter by virtue of its design lends itself very conveniently to the measurement of circuits under conditions of normal bias and operating voltages. Since there is a d.c. path between the bridge terminals with a d.c. resistance in the order of 66 ohms, biasing currents up to 50 ma can be introduced through the bridge and the component in the manner shown in Figure 1. In using this particular circuit the capacitor C should be made large enough so as to have negligible reactance at the operating frequency. It is desirable to use a d.c. source having a much higher voltage than required, and reducing the voltage through resistor R. By keeping R high the effect of the D.C. supply source is minimized.

For measurements requiring biasing currents in excess of 50 ma the circuit shown as Figure 2 is suggested. In this arrangement the biasing current circumscribes the bridge and therefore there are no restrictions imposed upon its magnitude. Here again it is desirable to keep C large enough to have negligible reactance. Since the purpose of the R.F. choke is to isolate the d.c. voltage source its inductance should be high. To preclude the possibility of any error due to the power supply, certain precautionary steps can be taken. Before attaching the test specimen, balance the instrument with the D.C. supply circuit alone. If the range of the balance controls is insufficient, balance the instrument by itself and measure the Cp and Rp of the D.C. supply circuit alone. The subsequent readings of the test specimen can then be corrected (for the effect of the D.C. supply circuit) as follows:

\[
C_{px} = C_{x0} - C_0
\]

where

- \(C_{px}\) = Cp of specimen
- \(C_{x0}\) = Cp of specimen & d.c. supply
- \(C_0\) = Cp of d.c. supply alone

\[
R_{px} = \frac{R_O \times R_{ox}}{R_O - R_{ox}}
\]

where

- \(R_{px}\) = Rp of specimen
- \(R_O\) = Rp of d.c. supply alone
- \(R_{ox}\) = Rp of d.c. supply & specimen

The basic circuits shown in Figures 1 & 2 can be modified or expanded as required to allow measurements to be made of the desired parameters in many types of circuits. Some typical arrangements are given in Figures 3 to 9. In Figures 3 (tube input impedance) and 4 (crystal diode impedance) it should be noted the ground shown by dotted line is the circuit ground and is not connected to the instrument ground. Figures 5 to 9, for which the author is indebted to the "Radio Development & Research Company" of Jersey City, New Jersey, are examples of some typical circuits employed in the measurement of transistors.

One factor that bears consideration in the measurement of vacuum tubes, transistors, and diodes is the level of the r.f. voltage applied to the component under test. With the RX Meter this is in the order of from 0.1 to 0.5 volts r.m.s. Should...
the constants of the circuit be such that this level cannot be tolerated, the addition of a 2 watt, 50,000 ohm potentiometer, mounted in a louvre hole in the rear of the instrument and wired according to Figure 10 to reduce the oscillator B+ voltage, makes it possible to lower the applied r.f. voltage down to 0.02 volts with satisfactory sensitivity during the measurement.

Measurement of the Self-Resonant Frequency of a Coil
This procedure consists of finding the frequency at which the inductive and capacitive reactances of the coil are equal (and opposite), and the coil itself looks like a pure resistance. The logical way to do this would be to set the Cp dial equal to zero and vary the frequency to obtain a null on the indicating meter. However, since it is necessary on the RX Meter 250-A to peak the "detector tuning" when operating the instrument at the higher frequencies, the self-resonant frequency is found by making two or three rapid preliminary measurements, balancing the instrument, and obtaining the final value.

The actual modus operandi is as follows:
1. Set up the bridge in accordance with the preliminary instructions given in the instruction manual. For the first approximation select a frequency higher than the estimated self-resonant frequency.
2. Mount the coil on the instrument and measure it in a normal manner. If the Cp dial reads in the capacitive range, the frequency is too high and should be lowered for the next approximation. Conversely, if the Cp dial indicates an inductance the frequency should be increased. The frequency change necessitated can be sensed from the effect on the Cp dial reading of the previous change.
3. When the Cp dial reads within 1 or 2 mfd of the zero line, remove the coil and balance the bridge before making the final reading.

It should be noted that while some manipulation of the Rp dial and some adjustment of the "detector tuning" knob might be needed in making the rough approximations, it is necessary to adjust the initial balance of the bridge only for the final measurement.

With those coils having multiple resonances, the alternate parallel and series points can be identified by the accompanying high or low values of parallel resistance indicated on the Rp dial. The lowest parallel self-resonant frequency is the one used in the determination of distributed capacity discussed below.

Measurement of the Distributed Capacitance (Cd) of a Coil
To consider an old friend very briefly, the expression for the resonant frequency of a series tuned circuit is:

$$ f = \frac{1}{2\pi \sqrt{LC}} \quad (1) $$

This same relationship obtains with a parallel tuned circuit, for all practical purposes, if the Q is ten or greater. For the purpose of our discussion we shall consider coils falling in this category.

Referring to (1) above, if the inductance is held constant but the capacitance changed to a new value, C2, then:

$$ \frac{f_1}{f_2} = \frac{\sqrt{C_2}}{\sqrt{C_1}} \quad (2) $$

If, in the case of a coil, f1 is the self-resonant frequency of f2, and C1 is the distributed capacity of the coil, C2, the relationship then becomes,
read directly off the silver portion of the C, dial on the RX meter when the bridge is balanced.

Thus to measure the C, of a coil on the RX meter it is necessary to determine its self-resonant frequency, set the bridge at 0.707 times this frequency, and measure the C, directly on the C, dial.

**Measurement of Tuned Circuits**

Very often it is necessary to measure the R, or Q of a tuned circuit at its resonant frequency. Since under these conditions the circuit is essentially resistive, it merely necessitates operating the RX Meter at the resonant frequency, verifying the resonant condition by insuring the C, dial reads zero, and reading the dynamic reactance directly off the R, dial. Conversely, the RX Meter can be set at the desired frequency and the tuned circuit adjusted for resonance as evidenced by a null on the indicating meter. Having the R, and being able to measure or compute either reactance, the Q of the tuned circuit can be determined from the relationship, 

\[
Q = \frac{R_o}{X_c}.
\]

By setting the RX Meter 250-A to the desired frequency, and the R, and C, dials to the required values, the instrument adapts itself to the tuning of pi-coupled matching networks used on transmitters and to the adjustment of line terminations, equalizers, and filters.

**Extension of Ranges**

The RX Meter 250-A has a parallel resistance range of 15 to 100,000 ohms and a parallel capacitance range from +20 mmfd to -100 mmfd. The negative symbol denotes an inductance and the quantity C, is the amount of capacitance required to resonate it. These ranges can be extended by the following means which are described for the particular extension desired.

**A. Manner of Extending Capacitance Range**

Referring to Figure 11, it can be seen that by using a smaller coil and adding a 100 mmfd capacitor externally across the bridge binding posts to be used in conjunction with the 100 mmfds on the Cp dial, it is possible to displace the original balance by 200 mmfd, and in this manner increase the capacitance range to 220 mmfd. The capacitance measurement thus becomes essentially one of substitution, since after the unknown is added to the terminals, balance is sought by removing capacity on the Cp dial, 0.1 mmfd at a time. If the measurement of the unknown is not made by the time the Cp dial reaches the +20 point, the 0.1 mmfd capacitor used for extending the range is removed, the Cp dial returned to -100 and the process repeated until balance is obtained. In this way although the range-extending capacity is added in an increment of 100 mmfd, it is removed by using the Cp dial in increments of 0.1 mmfd. In a like manner, other 100 mmfd capacitors, in conjunction with smaller coils, can be used to extend the range of capacitance measurement still further. A variable pre-
A precision capacitor is a very convenient device in these extensions since it increases the inductance latitude of the coil used for the extension. In all cases the value of capacity employed must be known since it is part of the calibration.

The inductance of the coil would then be shorted out rather than removed to avoid alteration of the physical configuration of the components which might otherwise affect the results. In dealing with extremely small inductance values, the inductance is obtained by

\[ L = \frac{1}{\omega^2 (C_p \text{ dial rdg} + \text{ ext. } C)} \]

or the reactance

\[ X_L = \frac{1}{\omega (C_p \text{ dial rdg} + \text{ ext. } C)} \]

In the above, external capacity is considered as having a negative sign as has \( C_p \) in this case. It has been found the range of measurement can be extended to include much smaller value of inductance by using an auxiliary resistor, connected in series with the “high” side of the coil. In this manner the overall Q is reduced which in turn allows smaller values of resonating capacitances in accordance with the relationship,

\[ L_{S} = \frac{C_p R_p^2}{1 + Q^2} \]

The value of the auxiliary resistor, which is not critical, depends upon the inductance to be measured and some idea of the required value can be obtained from the following table.

<table>
<thead>
<tr>
<th>INDUCTANCE REQUIRED RANGE (Microhenries)</th>
<th>REQUIRED RESISTOR (Ohms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>10 to 1000</td>
<td>1000</td>
</tr>
<tr>
<td>1 to 10</td>
<td>300</td>
</tr>
<tr>
<td>0.1 to 1</td>
<td>100</td>
</tr>
<tr>
<td>0.001 to 0.1</td>
<td>33</td>
</tr>
</tbody>
</table>

The value and accuracy of the auxiliary resistor is not critical and need only be of the correct order. The following procedure is suggested for such measurements:

a. Connect the unknown inductance in series with the auxiliary resistor across the RX Meter binding post. Using a minimum length of heavy, conducting strap, short the terminals of the inductance to remove it temporarily from the circuit.

b. Balance the bridge circuit and note the values of \( C_p \) obtained for the series resistor alone.

c. Remove the shorting strap from the inductive component, restoring the latter to the circuit, and rebalance the bridge. Note the values of \( R_2 \) and \( C_p \) for the series combination. Then the unknown inductance is obtained by

\[ L_{S} = \Delta C \left( R_p \right)^2 \]

where \( \Delta C = C_{p1} - C_{p2} \)

It should be noted that the inductance is shorted out rather than removed to avoid alteration of the physical configuration of the components which might otherwise affect the results. In dealing with extremely small inductance values, the inductance of the shorting strap itself will become significant and must be considered in interpreting the results.
Extension of the Rp Dial Below 15 Ohms

In dealing with low Q devices it is sometimes desirable to be able to measure resistance values below 15 ohms which is the lower limit of the direct-reading Rp scale.

At higher frequencies (in the neighborhood of 200 mc and above) the residual inductance of most components having series resistance values below 15 ohms such as low-value resistors, may be sufficient to increase the equivalent parallel resistance value above 15 ohms so that it may be measured directly. If not, a small inductance (having negligible series resistance) connected in series with the unknown will be sufficient to increase the Rp of the combination to the range of direct measurement.

At lower frequencies, the Rp of the unknown may be effectively increased for measurement by adding in series a small auxiliary resistor having a value preferably between 15 and 25 ohms. The series combination is measured and the values $R_{p1}$ and $C_{p1}$ are noted. The auxiliary resistor is then measured alone to obtain $R_{p2}$ and $C_{p2}$.

Then

$$R_S = R_{s1} - R_{s2} \quad \text{and}$$

$$L_S = L_{s1} - L_{s2}$$

Series resistance in each case would be

$$R_S = \frac{R_D}{1 + Q^2}.$$  

$C_{p1}$ and $C_{p2}$ can be changed to their respective values of inductance $L_{p1}$ and $L_{p2}$ in accordance with

$$L_S = \frac{C_pR_p^2}{1 + Q^2}.$$  

Conclusion

The foregoing discussion has not been presented in an effort to define the limits of the bridge, but rather to give some indication of its application in regions not readily apparent. As with any tool its ultimate potentialities are dependent upon the skill and ingenuity of the person using it.

**MECHANICAL DESIGN**

**REQUIREMENTS OF ELECTRONIC INSTRUMENTS**

David S. Wahlberg, Mechanical Design Engineer

---

**Figure 1. The Front Panel of the BRC Sweep Signal Generator Type, Type 240-A illustrates the final solution of a mechanical design problem involving mechanical placement, electronic function, nomenclature and esthetic factors.**

One of the most interesting and challenging phases in the design of an electronic instrument is that concerned with converting a set of specifications and a breadboard model into a practical, economical and useful product. It is at this stage of the endeavor that many of the problems become mechanical in nature.

**The Mechanical Designer's Problem**

From the moment the mechanical design of an instrument begins, a myriad of other considerations arise to confront what might otherwise seem a straightforward piece of electronic equipment. The mechanical designer must consider the electronic requirements of the Development and Project engineers, the functional and saleable appearance, weight and price insisted upon by Sales, and the mechanical urgencies of simple, rigid designs and drivers using the proper materials. In addition the Shop must be allowed reasonable tolerances within the limitations of available processes and equipment, Assembly should have units adapted to smooth work flow, and Inspection (and the user!) needs easy, accessible adjustments. Among many other factors are Purchasing's and Accounting's hopes that standard parts will be used, and Shipping's plea for enough unobstructed cabinet area to allow proper bracing in the packaging.

Thus, as those in industry know, any design comes about as the result of many compromises, all measured against the ultimate goal.

**The Front Panel**

Almost always, one of the first operations in the design program is the preparation of a front panel layout. However, this drawing also usually turns out to be the last one finished. A typical instance is the Sweep Signal Generator Type 240 A panel of Figure (2). The final symmetrical and functional grouping of the controls was arrived at after eleven distinct drawing revisions. Included were several major and many more minor changes, each one the result of discussion and action as the various problems of mechanical placement, electronic function, and clear titling were solved. As the give-and-take proceeds between esthetic and functional requirements versus circuit and control mechanism considerations, the front panel layout also starts to include the influences of framework and cabinet design.

**The Heat Dissipation Problem**

At this point the need for ventilation must be reckoned with. Close-accuracy instruments usually require heavy duty, constant voltage power supplies with much attendant heat. Therefore, such a power supply is usually separated from other
circuits as far as possible, either physically or by shielding, since it is the largest single source of heat. Once the power supply and other elements are located, and an estimate made of the heat to be dissipated, the ventilation paths and louvers are roughed out. Although most heat is carried off by convection if possible, the complete electrical shielding often needed around RF circuits prevent this. In these cases, heat must be conducted away by providing shields or heavy conductors leading to a large heat sink. Radiant heat is also a factor under these conditions. Bright metal shields can serve to "bottle up" a good deal of heat energy, whereas proper treatment of the surfaces will cause them to absorb and help dissipate heat.

Final word as to the adequacy of the cooling provided in an instrument usually awaits the completion of final temperature runs on the prototypes. Convection currents occasionally cause uneven heating of critical components, and such problems must be resolved by baffles or circuit adjustments before the design is completely "frozen."

Dealing with RF Leakage

The means of preventing RF leakage have a major influence in dictating the overall design layout. All circuits carrying heavy RF currents must be carefully botted up with leakage paths kept to a minimum. Control shaft holes particularly must be bridged by efficient shorting devices. The shafting necessary to operate an RF unit may often be just the right length to provide "bottle up" shielding the shell provides from extraneous fields. The tandem edge wipers, contacting all the rotor blades in parallel, serve to reduce the associated inductance and resistance to a very low and nearly constant value and are rhodium plated to provide good wearing qualities.

Where other considerations do not enter, rigidity is attained in the complete unit by mounting all the parts on a rigid cast frame. All shafts are carried on preloaded ball bearings.

The internal resonating capacitor might well be called the heart of the Q-Meter, and is an excellent example of the interdependence of mechanical and electrical design. Taking the 190-A Q unit as an example, the electronic requirements are low minimum capacitance, together with low and constant values of inductance and resistance all of which are difficult to attain in conventional designs. Mechanically the design must be extremely rigid to assure constant and accurate re-setability.

The massive structure ordinarily needed to attain the last-named end is in direct opposition to the minimum capacity requirement.

Reference to Figure (2) will show how satisfactory solutions were found for those conflicting needs.

The stator is mounted by means of two rods soldered into the metallized slots of a high quality ceramic support. Insofar as possible it floats in air dielectric. In addition, the rotor travel is restricted to less than 180°, with the included angle of the stator reduced by a proportionate amount to result in the largest possible angular gap between the two at the minimum setting. By these means the capacity at minimum was limited to the lowest value compatible with sufficient mechanical strength.

Low and constant inductance between the stator plates is achieved by milling out a solid bar to leave one shell and the plates, solidly connected with each other along their entire peripheries. A secondary result of this method is the "built-in" shielding the shell provides from extraneous fields.

The tandem edge wipers, contacting all the rotor blades in parallel, serve to reduce the associated inductance and resistance to a very low and nearly constant value and are rhodium plated to provide good wearing qualities.

Where other considerations do not enter, rigidity is attained in the complete unit by mounting all the parts on a rigid cast frame. All shafts are carried on preloaded ball bearings.

Conclusion

It is hoped that this brief description of instrument building from the mechanical point of view has shown how absorbing this part of the design effort can be, and that it is not separate unto itself but as much a part of the program as is the electronic design. Nevertheless a Mechanical Design Department would be something less than truthful for not admitting to the occasional feeling that it was also the focal point of almost everyone's problems. However, closer to the general truth is the plain fact that the Mechanical Designer has much a part of the program as is the electronic design.
EDITOR'S NOTE

Due to a mechanical error Fig.2 and Fig.3 in the previous issue (Spring, 1955) were interchanged. Also, the text in the captions at the foot of column 1 on page 7 should read "... was produced by the known low level output of the RF Voltage Standard." We shall try to avoid a repetition of this situation in the future.

Angle:

Figure 1. RX Meter showing location of Mixer, Ballast, and I.F. Amplifier tubes.

Operational problems with the RX Meter often can be traced to one of two sources:

Problem No. 1 concerns the mixer tube 6AB4.

Problem No. 2 concerns the ballast tube 6H-6.

Both problems are easily identified and corrected in the field. In most cases less time is needed to make the necessary repair than going through the formality of having a repair order issued. In some cases replacement of the 6H-6 with a 6H6 tube was all that was necessary to put the RX Meter back in operation. Be sure to turn the instrument off when checking operation of the RF Voltage Standard. We shall try to avoid a repetition of this situation in the future. The company supplies a specially selected 6AB4 tube, BRC #301637.

Incidentally, an increased null reading can also be caused by one or both 6AG5 tubes in the I.F. amplifier—V201 and V202—tried a few tubes and checking the null indication will tell the story.

To check voltages use voltage check chart of figure (2) below.

Figure 2. Voltage check chart
Dr. G. A. Downsbrough, President and General Manager of Boonton Radio Corporation, is shown above reviewing the card which he has just drawn to determine the winner of the Q Meter also shown in the picture. This Q Meter, displayed at our booth in the IRE Exhibits at Kingsbridge Armory in March, was to be awarded to one of our guests who completed a registration card at the booth.

The winning card was drawn from several thousand cards completed by our friends at the show and was signed by Mr. Waldemar Horizny, Technical Supervisor and Assistant Director of the Home Study Department, of RCA Institutes, Inc., of New York City. Mr. Horizny was born in Detroit, Michigan in 1921 and was awarded a BA degree from New York University in 1943. For a good number of years, he has been employed by RCA Institutes, Inc., a Service Company of Radio Corporation of America. Initially, he served as an instructor, and is now part of the Administrative Staff. His responsibilities entail supervising all technical operations of the Home Study Department, setting up courses of study, etc. His Department has prepared a Home Study Course in Television Servicing, and recently completed a Color Television Course. The department is now preparing a general radio and electronics course.

Mr. Horizny, in accepting the award, commented: "The Boonton Q Meter is no stranger, as it is no stranger to many other workers in the field. I have used the instrument in classroom instruction and for work related to the preparation of our courses."

Mr. Horizny lives at 138 Cypress Street in Floral Park, New York. He expects to use his Q Meter in his work for a period of time after which he will move it to his home laboratory.

We wish to thank all of the people who came by to see our exhibit at the IRE. We'll welcome you at future shows.
